### 4.1 Regulation of the Barents Sea Capelin Fishery

Since 1979, the Barents Sea capelin fishery has been regulated by a bilateral fishery management agreement between Russia (former USSR) and Norway. A TAC has been set separately for the winter fishery and for the autumn fishery. In recent years no autumn fishery has taken place, except for a small Russian experimental fishery. The fishery was closed from 1 May to 15 August until 1984. During the period 1984 to 1986, the fishery was closed from 1 May to 1 September. A minimum landing size of 11 cm has been in force for several years. From the autumn of 1986 to the winter of 1991, and from the autumn 1993 to the winter 1999 no fishery took place. The fishery was re-opened in the winter season 1991 and again in the winter season 1999, on a recovered stock.

In its autumn meeting of 2003, ACFM considered a harvest control rule, which was consistent with the precautionary approach. This rule defined the harvest level based on a maximum probability of $5 \%$ that SSB would fall below $\mathbf{B}_{\mathrm{lim}}$ of 200000 t (corresponding to no catch of pre-spawning capelin in 2003). ACFM also recommended that this harvest control rule be applied in 2003. (See also paragraph 4.5). During its Autumn 2003 meeting the Mixed Russian Norwegian Fishery Commission decided that no fishing should take place on Barents Sea capelin for the winter season 2004.

In 2002, the Mixed Russian Norwegian Fishery Commission agreed to adopt a management strategy based on the rule that, with $95 \%$ probability, at least 200000 t of capelin should be allowed to spawn.

### 4.2 Catch Statistics

The international catch by country and season in the years $1965-2003$ is given in Table 4.2.1. The catch by age and length groups during the spring season 2003 is given in Table 4.2.2. The total catch in winter 2003 given in Table 4.2.1 was 282000 t . This is 28000 t below the quota set for 2003. No catches were taken during autumn 2003.

### 4.3 Stock Size Estimates

### 4.3.1 Larval and 0-group estimates in 2003

Norwegian larval surveys based on Gulf III plankton samples have been carried out in June each year since 1981. The estimated total number of larvae is shown in Table 4.3.1.1. These larval abundance estimates do not show a high correlation with year class strength at age one, but should reflect the amount of larvae produced each year (Gundersen and Gjøsæter, 1998). The year 1986 was exceptional, in that no larvae were found. This may have been due to late spawning that year, and eggs may have hatched after the survey was carried out. Also in other years some spawning is known to have taken place during the summer, and offspring from such late spawning is not reflected in the larval abundance estimates in Table 4.3.1.1. Since 1997, permission has not been granted to enter the Russian EEZ during the larval survey or permission has been granted so late that it could not be employed to good purpose, and consequently the total larval distribution area has not been covered. The estimate of $11.9 \cdot 10^{12}$ larvae in 2003 is half of the estimate in 2002, at the same level as that obtained in 2001 and above the average for the period 1981-2003. During the international 0 -group surveys in August an area-based index for the abundance of 0 -group capelin is calculated (Table 4.3.1.1). Gundersen and Gjøsæter (1998) found these indices to be well correlated ( $\mathrm{r}^{2}=0.75$ ) with the 1-group acoustic estimates for the same year class obtained by the annual capelin acoustic surveys in autumn. Data points up to 1994 were included in this analysis. When this regression is updated with the survey results from 1981-2003 the parameters in the regression were changed slightly and the $\mathrm{r}^{2}$ was reduced to 0.65 . Based on this regression, (ln 1-group estimate $=$ $-1.74+1.18 \cdot \ln 0$-group index), the 0 -group index obtained in 2003 of 630 would correspond to a year class strength of 347 billion one-year-olds in autumn 2004. A year class of this size would be about 1.6 times an average year class in the period 1972-2002.

### 4.3.2 Acoustic stock size estimates in 2003

Two Russian and three Norwegian vessels jointly carried out the 2003 acoustic survey as part of an ecosystem-survey during autumn (WD by Bogstad et al.). The coverage of the total stock was considered complete. The results from the survey are given in Table 4.3.2.1, and are compared to previous years' results in Table 4.3.2.2. The stock size was estimated at 0.5 million tonnes. About $50 \%$ ( 0.28 mill t) of the stock biomass consisted of maturing fish ( $>14 \mathrm{~cm}$ ).

### 4.3.3

Other surveys
During the period of 20/02-08/03, two Russian research vessels surveyed and good coverage the area of capelins spawning stock distribution. It was about 99 thousand square nautical miles and located in the Norwegian, Russian and Grey Zones. Capelin as very scattered concentrations were recorded in the area from the $32^{\circ}-37^{\circ}$ everywhere. Typical "moving schools" practically were not found. The most part of fish was dispersed in the layers close to the bottom. It was weak migration $\mathbf{F}_{\text {low }}$ in the central part and there was not a considerable $\mathbf{F}_{\text {low }}$ in the east of the Barents Sea. The maturing stock, determined as the part of the stock exceeding 14 cm length, was estimated at $\mathbf{5 2 2 4 . 4 2 \times 1 0}{ }^{\mathbf{6}}$ ind., and $104.95 \times 10^{\mathbf{3}}$ tonnes. Capelin at the age of 3 and 4 (poor year-classes of 2001 and 2000) made up the bulk of the capelin spawning stock, in 28/60 proportion, in spring 2004.

During the Norwegian demersal fish survey in February 2004 observations of capelin by acoustics and by pelagic and demersal trawls were made. Although no stock size estimate was attempted, due to inadequate coverage and low number of pelagic trawl hauls for identification and sampling purposes, the overall impression was very low abundance of capelin found pelagically and sporadic catches of capelin in the bottom trawl hauls. Samples of cod stomachs during this period give valuable information for the modelling of maturing capelin as prey for cod (Bogstad and Gjøsæter, 2001).

### 4.4 Historical stock development

An overview of the development of the Barents Sea capelin stock in the period 1991-2003 is given in Tables 4.4.14.4.7. The methods and assumptions used for constructing the tables are explained in Appendix A to ICES 1995 Assess: 9. In that report, the complete time series back to 1973 can also be found. It should be noted that several of the assumptions and parameter values used in constructing these tables differ from those used in the assessment. For instance, in the assessment model the M-values for immature capelin are calculated using new estimates of the length at maturity and M -values for mature capelin are calculated taking the predation by cod into account. This will also affect the estimates of spawning stock biomass given in the stock summary table (Table 4.4.7). It should be noted that these values, coming from a deterministic model cannot directly be compared to those coming from the probabilistic assessment model (Bifrost) used for this stock. However, as a crude overview of the development of the Barents Sea capelin stock the tables may be adequate.

Estimates of stock in number by age group and total biomass for the period are shown in Table 4.4.1. Catch in numbers at age and total landings are shown for the spring and autumn seasons in Tables 4.4.2 and 4.4.3. Natural mortality coefficients by age group for immature and mature capelin are shown in Table 4.4.4. Stock size at 1 January in numbers at age and total biomass is shown in Table 4.4.5. Spawning stock biomass per age group is shown in Table 4.4.6. Table 4.4.7 gives an aggregated summary for the entire period 1973-2003.

### 4.5 Stock assessment autumn 2003

As decided by the Northern Pelagic and Blue Whiting Fisheries Working Group at its 2003 meeting (ICES 2003/ACFM:23), the assessment of Barents Sea capelin was left to the parties responsible for the autumn survey, i.e. IMR in Bergen and PINRO in Murmansk, who reported directly to ACFM before its autumn 2003 meeting (Bogstad et al., WD).

A probabilistic projection of the spawning stock to the time of spawning at 1 April 2004 was presented, using the spreadsheet model CapTool (implemented in the @RISK add-on for EXCEL). The projection was based on a probabilistic maturation model with parameters estimated by the model Bifrost (Gjøsæter et al. 2002) with uncertainty taken into account and data on size and composition of the cod stock (from the Arctic Fisheries Working Group, ICES 2003/ACFM:22, but made probabilistic in CapTool in accordance with the risk analysis made by the Arctic Fisheries Working Group). It was very good relationship between results of calculation SSB which geting by CapTool model and Russian winter capelin survey.

There is clearly a need for a target biomass reference point for capelin. Calculations of $\mathrm{B}_{\text {target }}$ were attempted, but were not presented because the results were considered preliminary. A $\mathbf{B}_{\mathrm{lim}}\left(\mathrm{SSB}_{\mathrm{lim}}\right)$ management approach was suggested for this stock. In 2002, the Mixed Russian Norwegian Fishery Commission agreed to adopt a management strategy based on the rule that, with $95 \%$ probability, at least 200000 t of capelin should be allowed to spawn. Consequently, 200000 t was used as a $\mathbf{B}_{\text {lim }}$.

Probabilistic prognoses for the maturing stock from October 12003 until April 12004 were made, with a CV of 0.20 on the abundance estimate. The meeting concluded that capelin recruitment in 2004 could be seriously negatively affected by the stock of young herring now found in the Barents Sea.

ACFM at its autumn 2003 meeting (ICES 2003/CRR:261) took all the points in the report into account. ACFM advised that no fishing should take place in spring 2004. This was based on adopting the forecast of the SSB using the limit reference points referred above, and following the harvest control rule that the SSB should fall below $\mathbf{B}_{\text {lim }}$ with a maximum $5 \%$ probability. ACFM also considered that adjustments of the harvest control rule should be further investigated for the purpose of taking better account of the uncertainty in the predicted estimate of spawner abundance, the likely interactions with herring, and the role of capelin as prey.

### 4.6 Management considerations

Since the assessment of the stock is directly based on the acoustic survey conducted annually in September-October, and the main fishing season does not begin until January, advice for this stock must be given during the autumn ACFM meeting and the TAC must be set by the Mixed Norwegian-Russian Fishery Commission during its meeting in November-December. As previously decided by the Northern Pelagic and Blue Whiting Fisheries Working Group, the assessment of Barents Sea capelin is left to the parties responsible for the autumn survey, i.e. IMR in Bergen and PINRO in Murmansk, who will meet in Kirkenes from 05-08 October 2004 and report directly to the 2004 ACFM autumn meeting.

### 4.7 Sampling

The sampling from scientific surveys and from commercial fishing on capelin in 2003 and winter 2004 is summarised below:

| Investigation | No. of samples | Length measurements | Aged individuals |
| :--- | :---: | :---: | :---: |
| Russian capelin investigation winter 2003 | 135 | 4808 | - |
| Russian fishery winter-spring 2003 | 114 | 19449 | 800 |
| Norwegian capelin investigations winter 2003 | 163 | 5581 | 1742 |
| Norwegian fishery winter-spring 2003 | 44 | 4340 | 1461 |
| Acoustic survey autumn 2003 (Norway) | 196 | 7707 | 2231 |
| Acoustic survey autumn 2003 (Russia) | 142 | 7330 | 725 |
| Other samples 2003 (Norway) | 139 | 8500 | - |
| Other sample 2003 (Russia) | 79 | 5739 | 50 |
| Norwegian capelin investigations winter 2004 | 213 | 6590 | 1994 |
| Russian capelin investigation winter 2004 | 167 | 9368 | 883 |

Table 4.3.2.1 Barents Sea CAPELIN. Estimated stock size from the acoustic survey in September-October 2003. Based on TS value $19.1 \log \mathrm{~L}-74.0 \mathrm{~dB}$, corresponding to $\sigma=5.0 \cdot 10^{7} \cdot \mathrm{~L}^{1.91}$.

Based on TS value: $19.1 \log \mathrm{~L}-74.0$, corresponding to $\sigma=5.0 \cdot 10^{-7} \cdot \mathrm{~L}^{1.9}$

Table 4.3.2.2 Barents Sea CAPELIN. Stock size in numbers by age, total stock biomass and biomass of the maturing component. Stock in numbers (unit: $10^{9}$ ) and stock and maturing stock biomass (unit: $10^{3}$ tonnes) are given at 1 . October.

| Year | $\text { Stock in numbers }\left(10^{9}\right)$ |  |  |  |  |  | Stock in weight ('000 t) |  |

Table 4.4.7 Barents Sea CAPELIN. Stock summary table. Recruitment (number of 1 year old fish (unit: $10^{9}$ ) and stock biomass (' 000 t ) given at 1 . August, spawning stock (' 000 t ) at time of spawning (1. April). Landings (' 000 t ) are the sum of the total landings in the two fishing seasons within the year indicated. The SSB is obtained by projecting the stock forward assuming a natural mortality that does not take the current predation mortality fully into account.

| Year | Stock biomass | Recruitment Age 1 | Spawning stock biomass | Landings |
